TRUCK LOADS ON PIPE BURIED AT SHALLOW DEPTHS

By
Richard W. Bonds, P.E.
DIPRA Research/Technical Director

Depth of cover less than 2¹/₂ feet is generally not recommended under roads and highways due to the possibility of high dynamic loading. Such loadings could result in damage to the pavements and/or the pipes. If impact factors higher than 1.5 (which is used in this paper) are anticipated, then such should be employed. For any given project, the ultimate responsibility for the proper use of the equations and other data provided in this paper rests with the design engineer. Call DIPRA with questions before applying this paper.

The procedure for calculating truck loads on buried Ductile Iron pipe is provided in ANSI/AWWA Standard C150/A21.50.¹ This procedure is based on the teachings of Merlin Spangler and others and utilizes the same procedures used in the venerable design standard ANSI A21.1² for Cast Iron pipe. The design method is based on two assumptions:

1. A single concentrated wheel load at the surface, and
2. Uniform load distribution over an effective pipe length of 3 feet.

The truck load on pipe buried under flexible pavement is given by Equation 5 in ANSI/AWWA C150/A21.50. It is shown below as Equation 1.

Equation 1

$$P_t = RF \frac{CP}{bD}$$

where

- P_t = Truck load in pounds per square inch
 R = Reduction factor (see Table 4 in C150/A21.50). This factor takes account of the fact that the part of the pipe directly below the wheels receives the truck superload in its full intensity but is aided in carrying the load by adjacent parts of the pipe that receive little or no load from the truck
 F = Impact factor of 1.5 (this is consistent with ASCE Manual No. 37)³
 C = Surface load factor
 P = Wheel load in pounds (for design purposes, 16,000 lbs., for a single AASHTO H-20 truck on unpaved road or flexible pavement)
 b = Effective pipe length of 36 inches
 D = Outside diameter of the pipe in inches

The surface load factor, C , is a measure of how the wheel load at the surface is transmitted and distributed through the soil to the pipe. C is given by Equation 6 in C150/A21.50 and is shown here as Equation 2.

Equation 2

$$C = 1 - \frac{2}{\pi} \text{ARCSIN} \left[H \sqrt{\frac{A^2 + H^2 + 1.5^2}{(A^2 + H^2)(1.5^2 + H^2)}} \right] + \frac{2}{\pi} \left(\frac{1.5 AH}{\sqrt{A^2 + H^2 + 1.5^2}} \right) \left[\frac{1}{A^2 + H^2} + \frac{1}{1.5^2 + H^2} \right]$$

NOTE: Angles are in radians.

where

- H = Depth of cover in feet
 A = Outside radius of the pipe in feet

This equation for the surface load factor, C , is derived from Holl's integration of the Boussinesq formula for vertical unit pressure, assuming the load is to be determined on a 3-foot section of pipe directly under the point load.⁴

Regarding the point load assumption, the following Boussinesq equation (Equation 3) gives the vertical stress at any point in an elastic medium when a point load is exerted at the surface,

Equation 3

$$\sigma_z = \left(\frac{3P}{2\pi} \right) \left(\frac{H^3}{R_1^5} \right)$$

where

- σ_z = Vertical stress in pounds per square inch
 P = Point load at surface in pounds
 H = Depth in inches
 R_1 = Distance from the point load to the point at which the stress is to be determined in inches (See Figure 1)

Figure 1 Single Wheelload

Integration of the Boussinesq equation (Equation 3) over the rectangular area over the pipe (as shown in Figure 1) results in the total load on a 3-foot section of pipe due to the point load, P , at the surface. Equation 2 is a function of this integration. The bD in the denominator of Equation 1 yields the desired units of pounds per square inch in expressing the truck load. The result thus represents an “average” pressure on the 3-foot length of pipe centered under the load.

The factors discussed above as well as other factors such as the assumed flexible pavement, the large wheel load used for design, the safety factors in the thickness design procedure, and the inherent structural strength of Ductile Iron,⁵ lead to the conclusion that the above approach to calculating truck loading is adequate at any depth of cover. Quite obviously, the actual distributed load of a truck tire “footprint” will produce less concentrated effects on a pipe than will the assumed “point” load. The typical dual truck tire imprint may have a contact area of approximately 200 square inches.⁶ Also, the length of pipe “effective” in carrying the load may be much greater than that assumed, particularly for large-diameter pipe. Further, in shallow cover situations under highways, the road bed stability will necessitate well-compacted fill around the pipe, which will increase its load bearing capacity.

Included herein for convenience is Table 1 (Earth Loads P_e , Truck Loads P_t , and Trench Loads P_v), Table 2 (Surface Load Factors for Single Truck on Unpaved Road), and Table 3 (Thickness for Earth Loads Plus Truck Loads), which can be used in the same manner as Tables 1, 6, and 12 in ANSI/AWWA C150/A21.50, respectively.
